

# Deep Structured Learning (IST, Fall 2019)

## Homework 4

**Instructors:** André Martins and Vlad Niculae

**TAs:** Gonçalo Correia and Ben Peters

**Deadline: Friday, December 13, 2019.**

Please turn in the answers to the questions below together with the code you implemented to solve them (when applicable). Please email your solutions in **electronic format** (a single zip file) with the subject “Homework 4” to:

`deep-structured-learning-instructors@googlegroups.com`

**Hard copies will not be accepted.**

### Question 1

**Transliteration.** Transliteration is the problem of converting text (usually entity names) from one script to another. For example, `васильевич` in Russian (Cyrillic script) is transliterated as `Vassiljevitch` in English (Latin script). We can regard this as a sequence-to-sequence problem, where the sizes of the two sequences do not necessarily match.

In this exercise, we will use the Arabic-English transliteration data released by Google (<https://github.com/googlei18n/transliteration>).

Run the following commands to download the train, validation, and test partitions (resp. 12877, 1431, and 1590 word pairs):

```
wget https://raw.githubusercontent.com/googlei18n/transliteration/master/ar2en-train.txt
wget https://raw.githubusercontent.com/googlei18n/transliteration/master/ar2en-eval.txt
wget https://raw.githubusercontent.com/googlei18n/transliteration/master/ar2en-test.txt
```

1. You are going to implement a sequence-to-sequence model for this task. The input and output should respectively be an Arabic and a English word, represented left-to-right as a sequence of characters. The evaluation metric is Word Accuracy (which counts the fraction of words that were fully transliterated correctly).
  - (a) (10 points) Start by determining the source and target vocabularies (don't forget to include special symbols, such as `START`, `STOP`, `UNK`, and `PAD` (if you pad). What are the vocabulary sizes?
  - (b) (30 points) Implement a vanilla sequence-to-sequence model using an encoder-decoder architecture with two unidirectional LSTMs (one encoder LSTM and one decoder LSTM). Report the validation accuracy as a function of the epoch number and the final test accuracy. Hint: if you're using Pytorch, use the function `nn.LSTM` for this exercise.
  - (c) (10 points) Repeat the previous exercise reverting the source string.

- (d) (30 points) Turn the encoder into a bidirectional LSTM and add an attention mechanism to the decoder. Report the validation accuracy as a function of the epoch number and the final test accuracy.

## Question 2

**Baselines in reinforcement learning.** The REINFORCE algorithm commonly uses a “baseline” to reduce the variance of its parameter updates. In this exercise, you will prove the underlying result that makes this strategy possible.

- (10 points) Let  $x \in \mathcal{X}$  be a random variable distributed according to  $p_{\theta}(x)$ , where  $\theta \in \mathbb{R}^d$  is a parameter, and let  $f : \mathcal{X} \rightarrow \mathbb{R}$  be a function independent of  $\theta$ . Show that  $\nabla_{\theta} \mathbb{E}[f(x)] = \mathbb{E}[f(x) \nabla_{\theta} \log p_{\theta}(x)]$ , where the expectation is with respect to  $p_{\theta}$ .
- (10 points) Use the above fact to show that  $\mathbb{E}[\nabla_{\theta} \log p_{\theta}(x)] = 0$  and that  $\mathbb{E}[f(x) \nabla_{\theta} \log p_{\theta}(x)] = \mathbb{E}[(f(x) - b) \nabla_{\theta} \log p_{\theta}(x)]$  for any constant  $b \in \mathbb{R}$ . Comment how  $b$  can be used to reduce the variance of a Monte Carlo gradient estimator of  $\nabla_{\theta} \mathbb{E}[f(x)] \approx \frac{1}{k} \sum_{i=1}^k f(x_i) \nabla_{\theta} \log p_{\theta}(x_i)$ .
